Accepted: April 2016

Abstract

Three mesh sizes of multifilament trammel nets (22 mm, 24 mm, and 26 mm) were used in Finike bay for red mullet (*Mullus barbatus* L., 1758). The sampling program was arranged during February to May 2012. Holt (1963) method was used for selectivity of trammel nets. Red mullet was the dominant species in 22 mm mesh size at 52.86%, followed by 25.7% with the 24 mm net and 21.43% with the 26 mm net. On the basis of the results of this study, optimal selectivity lengths of multifilament trammel nets estimated for red mullet were 18.58, 20.27, and 21.96 cm for 22, 24, and 26 mm mesh size, respectively. Thus, based on length at first maturity it has been stated that the trammel nets of 22, 24, and 26 mm mesh size do not cause over fishing of the red mullet population in Finike Bay.

Introduction

Red mullet (*Mullus barbatus*) is one of the most important demersal fish species in Finike Bay. It is observed that there has been a drop in the fishery of red mullet due to improper fishing management and illegal fishing practices along the entire coastline of Turkey (Özbilgin *et al.*, 2004).

The trammel net is used widely as a fishing gear for the fishery of red mullet in Finike Bay. Although trammel nets are mostly passive fishing gears, they are used actively like cast nets (Kara, 1992). Trammel nets have trammels on both sides of a fine-mesh net. The fishing method relies on catching various fishery products passing through trammel net meshes and pocketed and trapped in the main net (Hoşsucu, 2009). Trammel nets are quite commonly used among fishermen in Turkey since they are less costly. Their construction and maintenance are carried out for small amounts of money (Kara, 1992; Bolat and Kuşat, 1997).

Among fishing gear, gillnets are considered to be highly fish size selective and important for fisheries management and the environment (İlkyaz, 2005). The selectivity of trammel nets is related to mesh size, fish size and shape. In addition the material and colour of the nylon of the net used, rigging factor, hanging ratio and type of fisheries are important to catch a much larger size range of fish (Clarke, 1960; Hamley, 1975; İlkyaz, 2005). However, the main factor that affects selectivity is the mesh size (Von Brandt, 1975). While trammel nets

catch individuals of certain size at an optimal level, they catch less individuals smaller and larger than the optimal size. As it goes beyond the optimal catch size, the effectiveness lowers down towards zero in both directions (Holt, 1963). Selectivity offers major facilities in stock management (Öztekin 2007). The basic principle of stock management is that allowing the growth and reproduction of small size fish and to prohibit their catch. Being familiar with the characteristics of the selectivity of the net used and the determination of appropriate mesh size allow providing guidance for fishermen and taking the necessary measures (Zengin *et al.*, 1997). However, a limited number of selectivity studies with trammel nets are available in Lake Van (Çetinkaya *et al.*, 1995), in Aegean Sea (Karakulak and Erk, 2008; Aydın and Sümer, 2010) and in the Gulf of Iskenderun (Akamca *et al.*, 2009), there are some studies on trawl codend selectivity, gillnets and trammel nets selectivity for red mullet in the Aegean, Mediterranean and other seas (Özekinci, 1997; Fabi *et al.*, 2002; Sala *et al.*, 2006; Aydın *et al.*, 2008; Dinçer and Bahar, 2008; Özbilgin *et al.*, 2011) but there is no study in the Finike Bay. In this study, we aimed to determine the selectivity of trammel for red mullet with different mesh sizes of nets in Finike Bay for sustainable fisheries management.

Material and methods

The study was conducted in Finike Bay in Antalya Province. The bottom

structure of the fishing area was sandy, muddy and rocky and depths varying from 11 m to 43 m (Fig. 1).

The experimental trammel nets were composed of three different mesh sizes 22 mm, 24 mm, and 26 mm in the inner panels consisting of nylon made of polyamid and 60 mesh depth with a hanging ratio of 0.50 and the outer panels had a mesh size of 140 mm (bar length) with mesh depth of 4.5 to 5.5 and hanging ratio of 0.50. Total length of the trammel was 900 m.

Float and lead lines comprise nylon PP with a diameter of 4 mm. While PE ϕ 2.5 and 3 no. floats were used for the float line, 30 g lead was used for the lead line (Table 1).

The study was carried out between February and May 2012. The nets were set a few hours before sunset and hauled after sunset. Nine fishing operations took place during the study. After each fishing operation, fishes were taken from the nets and categorized by mesh sizes and total lengths were measured to the nearest mm.

Selectivity parameters of trammel-nets for *M. barbatus* were estimated according to the indirect method proposed by Holt (1963). This method allows the estimation of selectivity parameters by comparing the catches in terms of quantity based on two different mesh sizes for the same length class.

Figure 1: Study Area

Table 1: Characteristics of the trammel nets used for the study.

IMS (mm)	IMD	OMS (mm)	Inner-net (PA)	Outer-net (PA)	Float ϕ	Lead	E
22	60-mesh	140	210D/2	210D/4	2.5	30 g	0.50
24	60-mesh	140	210D/2	210D/4	2.5	30 g	0.50
26	60-mesh	140	210D/2	210D/4	3	30 g	0.50

IMS: Inner panel- mesh size; IMD: Inner panel-mesh depth; OMS: Outer panel- mesh size; E: Hanging ratio; PA:Polyamid

The natural logarithms of the numbers caught per length group, C_a and C_b , by two slightly different mesh sizes, m_a and m_b , are linearly related to fish lengths; $\ln(C_b/C_a) = a + bL$,

Where L is the length class of caught fish, a and b are the intercept and slope of the linear regression, respectively.

The optimum lengths (L_{ma} and L_{mb}) for mesh sizes m_a and m_b , the selection factor (S_f) and standard deviation (S_d) were then estimated from the following equations:

$$L_{m_a} = -2 [a m_a / b (m_a + m_b)]$$

$$L_{m_b} = -2 [a m_b / b (m_a + m_b)] = L_{m_a} \cdot m_b / m_a \text{ and,}$$

$$S_f = -2 a / b (m_a + m_b)$$

$$S_d = \{-2 a (m_b - m_a) / b (m_a + m_b)\}^{1/2}$$

If the number of mesh sizes used are more than two, the common selectivity factor will be calculated as follows (Sparre *et al.*, 1989),

$$SF = -2 \sum [(a_i / b_i) (m_i + m_{i+1})] / \sum [(m_i + m_{i+1})^2] \text{ for } I = 1 \text{ to } n-1$$

The common standard deviation (SD) was calculated as the mean value of the individual estimates for each consecutive pair of mesh sizes,

$$SD = \{1 / (n-1) \sum [(2a_i (m_{i+1} - m_i)) / b_i 2(m_i + m_{i+1})]\}^{1/2}$$

The optimum length (corresponding to a 100% of probability of retention) for each mesh-sizes m was obtained as: $L_m = (SF) \times m$

The probability of capture (P) for a given length L in a gill net with mesh size m was determined from the following equation:

$$P = \exp [-(L - L_m)^2 / (2SD^2)] \text{ (Özekinci } et al., 2007; \text{Çat and Yüksel, 2014).}$$

While Microsoft Excel package program was used in plotting selectivity curves, analysis of variance (ANOVA, SPSS 15.0) was used for the comparison of the differences between average fish size and mesh size (Elbek *et al.*, 2002).

Results

Of the total 776 specimens caught by trammel nets in 9 fishing operations, 420 were the target species red mullet. The numbers of red mullet caught were 222, 108 and 90 in the 22, 24 and 26 mm mesh sizes, respectively. We observed that there was a decline in the amount of catch in numbers with increasing mesh sizes (Table 2).

There were significant differences between the mean length and mesh sizes ($p < 0.05$ $df=2$, $F=52.81$). During the study, selectivity parameters were calculated for red mullet, with a total number of 420 individuals. Length frequency values and natural logarithms of catch rate of red mullet caught by the different mesh sizes are given in Table 3.

Gradient and the point of intersection determined by applying regression analysis to the data given in Table 4 and optimal catch size, selectivity factors and standard deviation values were calculated and are given in Table 3. A plot of the length groups and different mesh size combinations indicated a linear relation. Therefore, a linear regression was fitted to the data of catch ratios (Figs. 2 and 3).

Discussion

Trammel nets are widely used for the harvest of fish. Because trammel nets are highly selective for fish of certain size, knowledge of the size selection of nets is necessary to effectively regulate their use and for population assessment.

The main objective of selectivity is to determine the optimal mesh size to increase target species ratio and to minimize by-catch and discard ratios for sustainable fishing (Hamley, 1975).

The selectivity of the set nets is important for the conservation of fish

stocks and sustainable fishing. One of the main principles for the sustainability of fish populations is to allow at least one to mature in its natural location. Hence, the minimum legal size of fish must be longer than the first maturity length (Öztekin, 2007).

Hovgard and Lassen (2000) have reported that selectivity factor is directly related to the body structure of fish as well as to design properties of the fishing material in the selectivity of nets. While, this value is high in thin and long body shapes namely fusiform

fish, this value decreases as far as the body thickens (stubby form). The selection curve of set nets are generally bell-shaped and vary depending on the morphological characteristics of the species (e.g. body shape, occurrence of spiny rays, teeth) and technical features of the net (e.g. materials, hanging ratio). The lower selectivity of trammel nets results in a skew to the right or left side of catch length-frequency distribution (Fabi *et al.*, 2002).

Özekinci (2005) reported that the estimated selectivity curves are assumed to be in the shape of a normal distribution and to be narrow. The shape of a selection curve is dependent on the difference between fish girth and mesh girth. If the difference is small, the selection curve will appear narrow, but a large difference will lead to a broader selection curve. This difference may be linked to the morphology of the anterior part of the fish.

In the present study, the selectivity of trammel nets with three different sized meshes (22, 24, and 26 mm) was evaluated for red mullet.

The largest catch of the red mullet was obtained with the 22-mm mesh size compared to 24 and 26 mm mesh sizes. The selectivity curves of red mullet showed normal distribution. The common selectivity factor (SF) and standard deviation (SD) of the nets were found as 8.44876 and 1.96865, respectively.

Özekinci (1997) determined that the factors of selectivity had varied from 7.12 to 6.82 for 18 - 20 mm and 20 - 22 mm nets for red mullet. The optimal

size of selectivity was found to have been between 12.97 and 14.41 and 13.64 and 15.0, respectively, for red mullet. In the present study, we observed that the differences between the factors of selectivity and optimal catch size determined for red mullet because of using different types and different mesh sizes of nets.

In a study carried out by using the SELECT Method along the Black Sea coastline for red mullet, optimal catch size was found as 14.24 cm, 16.02 cm, 17.8 cm, and 19.58 cm for the gill nets with mesh size 32 mm, 36 mm, 40 mm, and 44 mm, respectively. Although the nets hauled in the experiments and method used were different, optimal catch sizes of the nets for 22 mm mesh size were found to be similar to that reported by Dinçer and Bahar (2008) and Özekinci (1997), but was found different from results of Kalaycı and Yeşilçiçek (2012). 13 cm was the minimum landing size for red mullet reported in the fisheries regulations circular published by GTHB. The study carried out by Metin (2005) supported the minimum landing size on the first maturation size. The optimal catch size belonging to the nets with 22 mm mesh size used by fishermen in the Finike Bay is much greater than the minimum landing size. Moreover, only one red mullet individual smaller than 13 cm was caught with this mesh size during the sampling period.

In conclusion, this proves that the nets used for the study have not created fishing pressure on red mullet in Finike Bay and these trammel nets could be

used in the area for the sustainable fisheries of red mullet. The minimum mesh size of the trammel nets especially those used in red mullet fishery can be 22 mm considering also that other species can be caught.
